Introduction to Algorithms

Divide and Conquer: Finding Root Closest Pair of Points

Finding the Root of a Function

Finding the Root of a Function

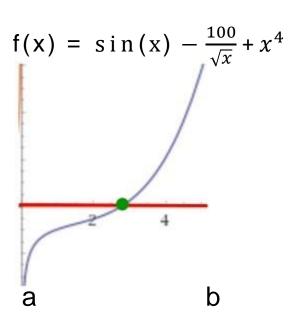

Given a continuous function f and two points a < b such that

Assumption
$$\begin{cases} f(a) \le 0 & \text{f(b)} \le 0 \\ f(b) \ge 0 \end{cases}$$

Find an approximate root of f (a point c where f(c)=0).

f has a root in
$$[a, b]$$
 by intermediate value theorem

Note that roots of f may be irrational, So, we want to approximate the root with an arbitrary precision!

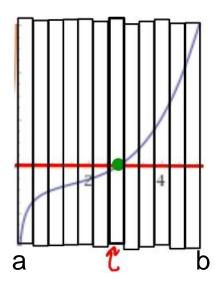

A Naiive Approch

Suppose we want ϵ approximation to a root.

Divide [a,b] into $n = \frac{b-a}{\epsilon}$ intervals. For each interval check $f(x) \le 0$, $f(x + \epsilon) \ge 0$

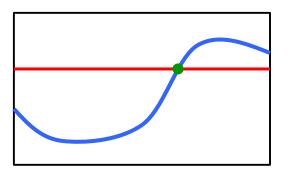

This runs in time $O(n) = O(\frac{b-a}{\epsilon})$

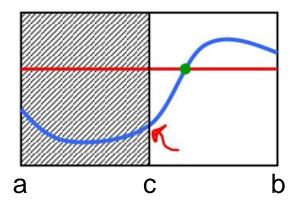

Can we do faster?

D&C Approach (Based on Binary Search)

```
Bisection(a,b, ε)
    if (b-a) < \epsilon then
       return (a)
    else
       c \leftarrow (a+b)/2
       if f(c) \le 0 then
          return(Bisection(c, b, \varepsilon))
       else
          return(Bisection(a, c, \epsilon))
```

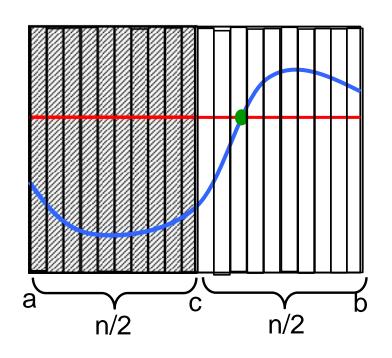

Time Analysis

Let
$$n = \frac{b-a}{\epsilon}$$

And $c = (a + b)/2$

Always half of the intervals lie to the left and half lie to the right of c

So,
$$T(n) = T(\frac{n}{2}) + O(1)$$
i.e.,
$$T(n) = O(\log n) = O(\log \frac{a-b}{\epsilon})$$

Recurrences

Above: Where they come from, how to find them

Next: how to solve them

Master Theorem

Suppose $T(n) = aT(\frac{n}{b}) + cn^k$ for all n > b. Then,

- If $a > b^k$ then $T(n) = \Theta(n^{\log_b a})$
- If $a < b^k$ then $T(n) = \Theta(n^k)$
- If $a = b^k$ then $T(n) = \Theta(n^k \log n)$

Works even if it is $\left\lceil \frac{n}{b} \right\rceil$ instead of $\frac{n}{b}$. We also need $a \ge 1$, b > 1, $k \ge 0$ and T(n) = O(1) for $n \le b$.

Master Theorem

Suppose $T(n) = aT(\frac{n}{b}) + cn^k$ for all n > b. Then,

- If $a > b^k$ then $T(n) = \Theta(n^{\log_b a})$
- If $a < b^k$ then $T(n) = \Theta(n^k)$
- If $a = b^k$ then $T(n) = \Theta(n^k \log n)$

Example: For mergesort algorithm we have

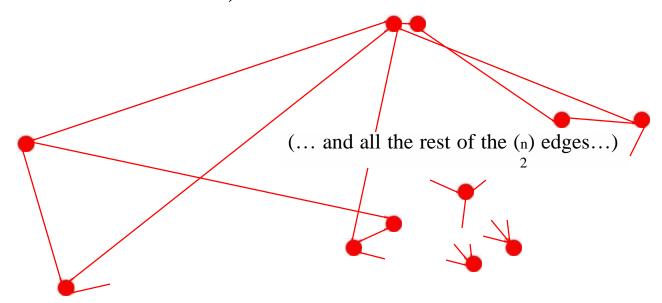

$$T(n) = 2T(\frac{n}{2}) + O(n).$$

So,
$$k = 1$$
, $a = b^k$ and $T(n) = \Theta(n \log n)$
 $T(n) = 5 T(\frac{n}{2}) + (n^2)$. $\alpha = 5$, $b = 2$, $c = 2$

Finding the Closest Pair of Points

Closest Pair of Points (non geometric)

Given n points and arbitrary distances between them, find the closest pair. (E.g., think of distance as airfare – definitely not Euclidean distance!)

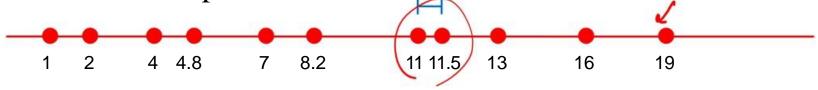

Must look at all n choose 2 pairwise distances, else any one you didn't check might be the shortest. i.e., you have to read the whole input

Closest Pair of Points (1-dimension)

Given n points on the real line, find the closest pair,

e.g., given 11, 2, 4, 19, 4.8, 7, 8.2, 16, 11.5, 13, 1 find the closest pair

Fact: Closest pair is adjacent in ordered list

So, first sort, then scan adjacent pairs.

Time O(n log n) to sort, if needed, Plus O(n) to scan adjacent pairs

Key point: do *not* need to calc distances between all pairs: exploit geometry + ordering

Closest Pair of Points (2-dimensions)

Given n points in the plane, find a pair with smallest Euclidean distance between them.

Fundamental geometric primitive.

Graphics, computer vision, geographic information systems, molecular modeling, air traffic control.

(3,1)

(-1, 5)

Special case of nearest neighbor, Euclidean MST, Voronoi.

Brute force: Check all pairs of points p and q with $\Theta(n^2)$ time.

Assumption: No two points have same x coordinate.

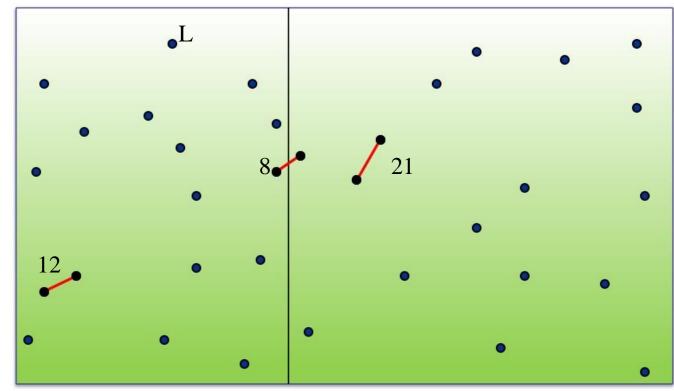

A Divide and Conquer Alg

Divide: draw vertical line L with $\approx n/2$ points on each side.

Conquer: find closest pair on each side, recursively.

Combine to find closest pair overall \leftarrow seems like $\Theta(n^2)$?

Return best solutions

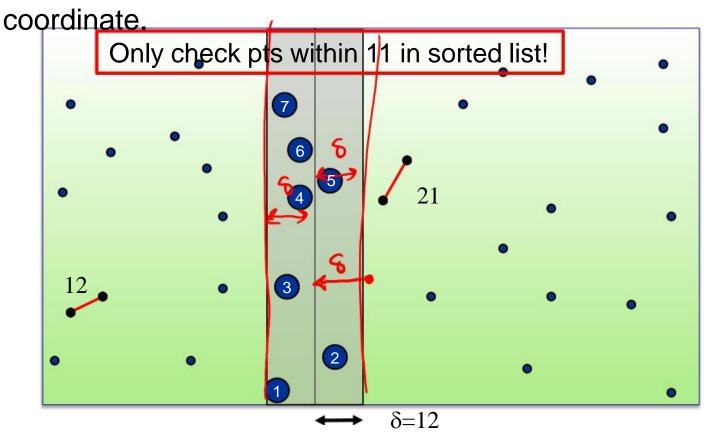

Key Observation

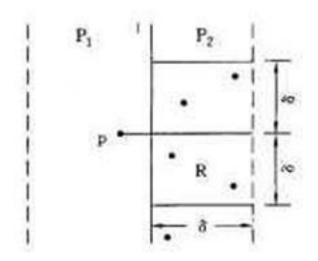

Suppose δ is the minimum distance of all pairs in left/right of L. $\delta = \min(12,21) = 12$.

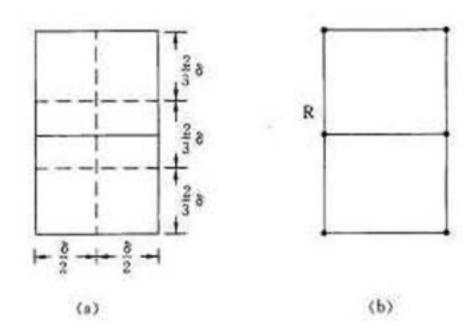

Key Observation: suffices to consider points within δ of line L.

Almost the one-D problem again: Sort points in 2δ-strip by their y

Key Observation

Closest Pair (2Dim Algorithm)

```
Closest-Pair(p1, ..., pn) {
   if(n <= ??) return ??
   Compute separation line L such that half the points
   are on one side and half on the other side.
   \delta_1 = Closest-Pair(left half)
   \delta_2 = Closest-Pair(right half)
   \delta = \min(\delta_1, \delta_2)
   Delete all points further than \delta from separation line L
   Sort remaining points p[1]...p[m] by y-coordinate.
   for i = 1..m
      Check nearest 6 nodes on the opposite size of p[i];
      Determine a shortest distance \delta';
      \delta = \min(\delta, \delta');
   return \delta.
```

Closest Pair Analysis I

Let D(n) be the number of pairwise distance calculations in the Closest-Pair Algorithm when run on $n \ge 1$ points

$$D(n) \le \begin{cases} 1 & \text{if } n = 1 \\ 2D(\frac{n}{2}) + 6n & \text{o.w.} \end{cases} \Rightarrow D(n) = O(n \log n)$$

BUT, that's only the number of *distance calculations* What if we counted running time?

$$T(n) \leq \begin{cases} 1 & \text{if } n = 1 \\ 2 T\left(\frac{n}{2}\right) + O(n \log n)^{\text{o.w.}} \end{cases} \Rightarrow D(n) = O(n \log n)$$

Proving Master Theorem

A Useful Identity

Theorem:
$$1 + x + x^2 + \dots + x^d = \frac{X^{d+1}-1}{x-1}$$

Pf: Let
$$S = 1 + x + x^2 + \dots + x^d$$

Then,
$$xS = x + x^2 + \dots + x^{d+1}$$

So,
$$xS - S = x^{d+1} - 1$$

i.e.,
$$S(x-1) = x^{d+1} - 1$$

Therefore,

$$S = \frac{X^{d+1} - 1}{x - 1}$$

Solve: $T(n) = aT(\frac{n}{b}) + cn^k$, $a > b^k$

$$T(n) = c n^{k} \sum_{i=0}^{\log_{b} n} \left(\frac{a}{b^{k}}\right)^{i}$$

$$= c n^{k} \frac{\left(\frac{a}{b^{k}}\right)^{\log_{b} n + 1} - 1}{\left(\frac{a}{b^{k}}\right) - 1}$$

$$= c n^{k} \frac{\left(\frac{a}{b^{k}}\right)^{\log_{b} n + 1} - 1}{\left(\frac{a}{b^{k}}\right) - 1}$$

$$b^{k\log_b n}$$

$$= (b^{\log_b n})^k$$

$$= n^k$$

$$b^{k\log_b n} = (b^{\log_b n})^k = n^k$$

$$\leq C \left(\frac{n^k}{b^{k\log_b n}} \right) \frac{\left(\frac{a}{b^k} \right)}{\left(\frac{a}{b^k} \right) - 1} a^{\log_b n}$$

$$\leq 2 c a^{\log_b n} = O(n^{\log_b a})$$

$$a^{\log_b n}$$

$$= (b^{\log_b a})^{\log_b n}$$

$$= (b^{\log_b n})^{\log_b a}$$

$$= n^{\log_b a}$$

Solve:
$$T(n) = aT(\frac{n}{b}) + cn^k$$
, $a = b^k$

$$T(n) = c n^{k} \sum_{i=0}^{\log_{b} n} \left(\frac{a}{b^{k}}\right)^{i}$$
$$= c n^{k} \log_{b} n$$

Master Theorem

Suppose $T(n) = aT(\frac{n}{b}) + cn^k$ for all n > b. Then,

- If $a > b^k$ then $T(n) = \Theta(n^{\log_b a})$
- If $a < b^k$ then $T(n) = \Theta(n^k)$
- If $a = b^k$ then $T(n) = \Theta(n^k \log n)$

Works even if it is $\left\lceil \frac{n}{b} \right\rceil$ instead of $\frac{n}{b}$.

We also need $a \ge 1$, b > 1, $k \ge 0$ and T(n) = O(1) for $n \le b$.
